Problem Statement

Develop a Gym Member Management System using Stack and Queue in C++ to store and manage gym member records. Each record contains the member's ID, name, and membership type. The system should provide a menu-driven interface that allows users to perform the following operations:

1. Insert Record: Add a new gym member's record to the Stack or Queue by entering the member's ID, name, and membership type.

2. Delete Record: Remove a member's record from the Stack using the LIFO (Last In, First Out) principle or from the Queue using the FIFO (First In, First Out) principle.

3. Display Stack Records: Display all member records stored in the Stack, starting from the top element and moving towards the bottom.

4. Display Queue Records: Display all member records stored in the Queue, starting from the front element and moving towards the rear.

5. Overflow Handling: Check whether the Stack or Queue is full before inserting a new member record and display an appropriate message if no space is available.

6. Underflow Handling: Check whether the Stack or Queue is empty before deleting a record and display an appropriate message if no record is available.

7. Exit: Allow the user to terminate the program after completing the required operations.
